

# Statistical models for planning the selective breeding against scrapie in sheep

Jón H. Eiríksson

Faculty of Agricultural sciences

Agricultural University of Iceland

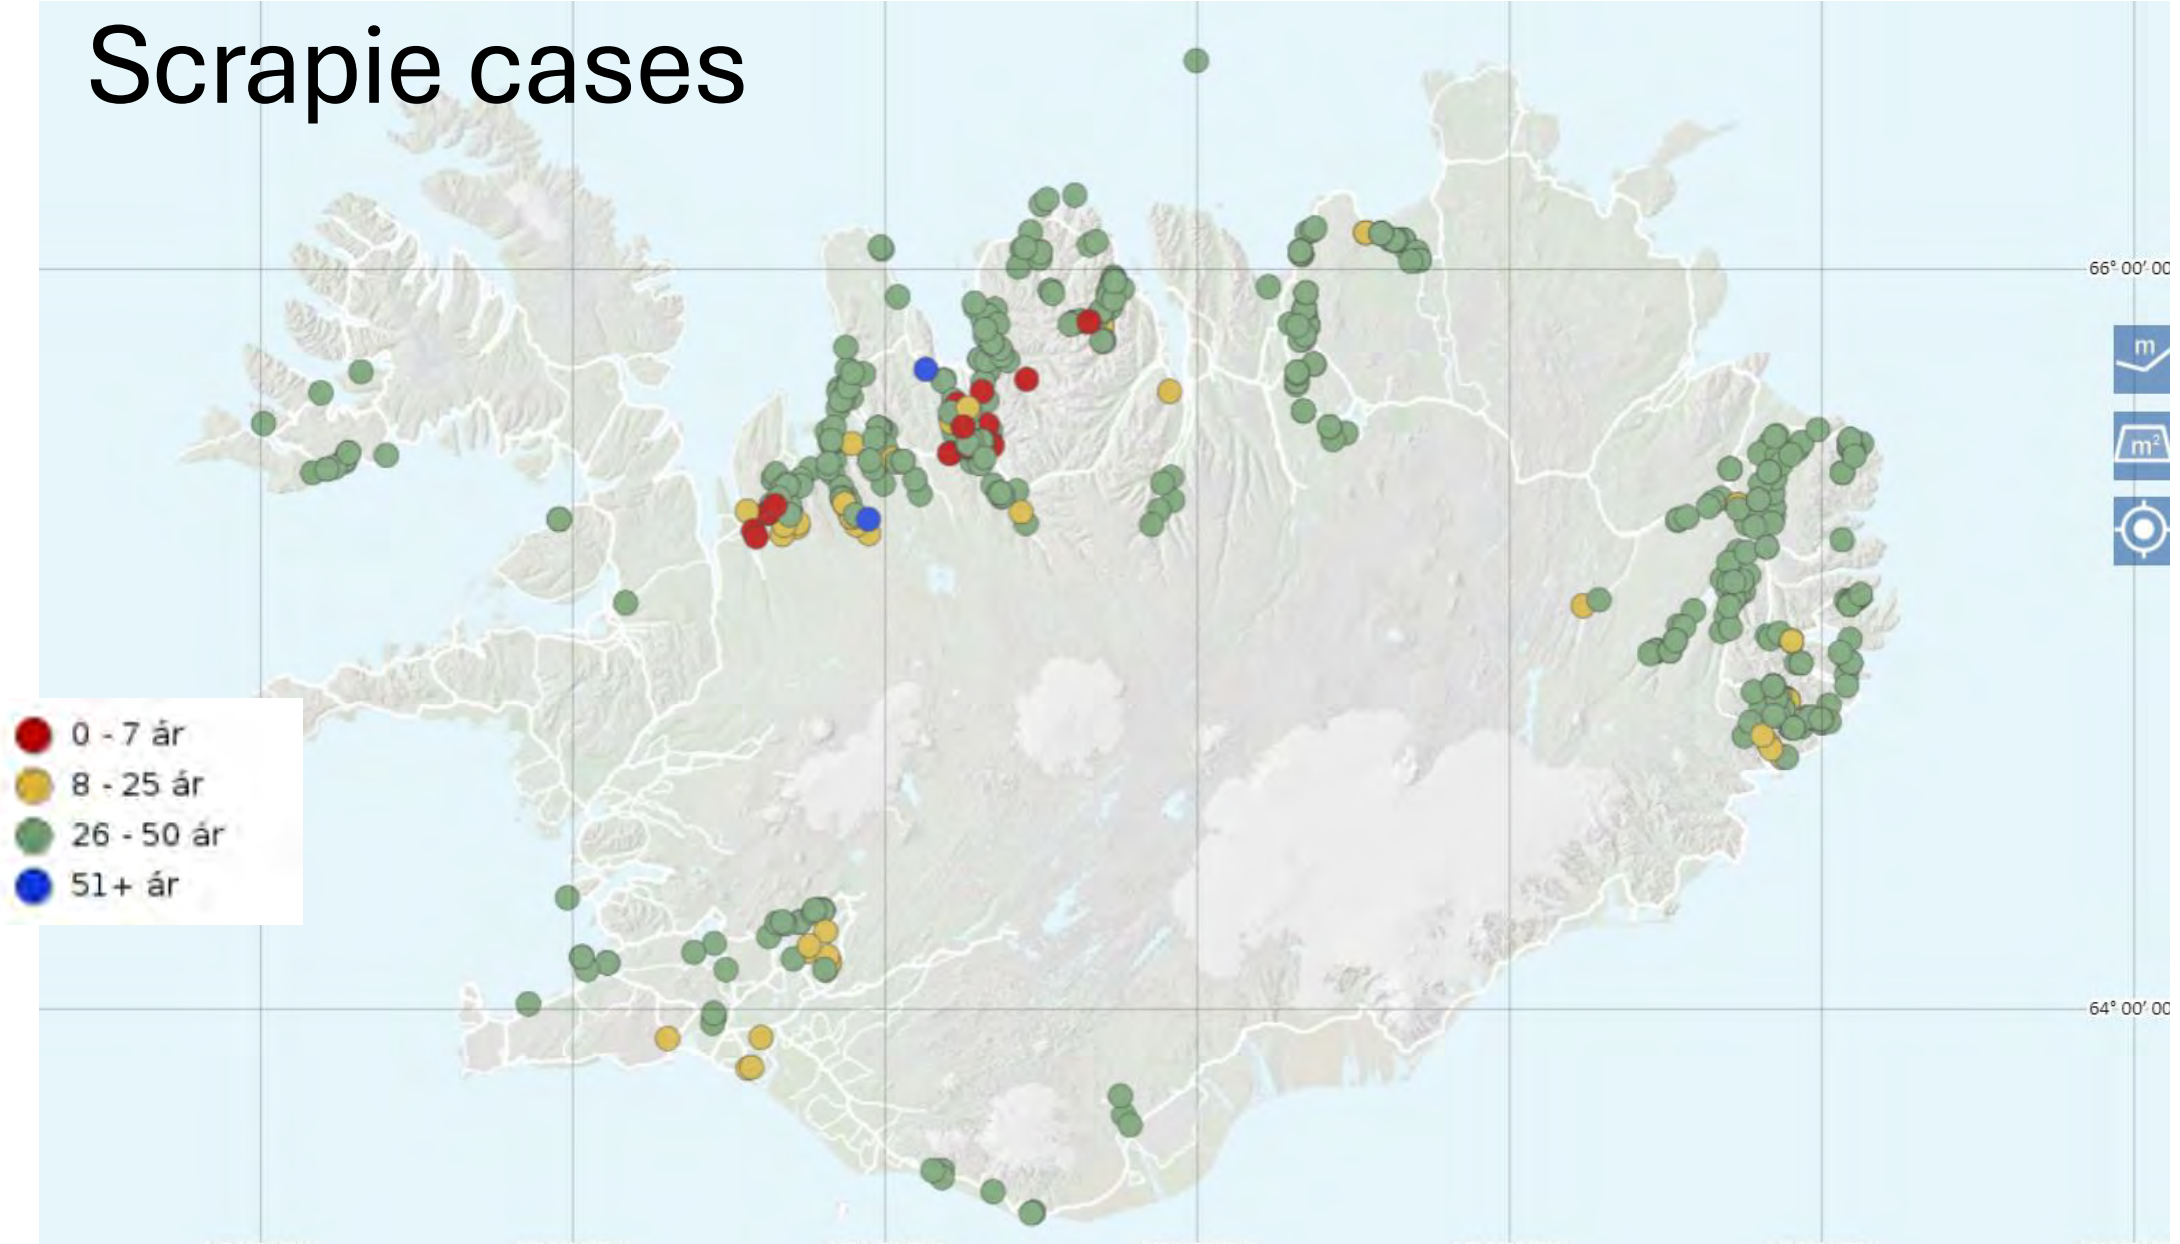

# Scrapie

One of the transmissible spongiform encephalopathies (TSEs), prion diseases

BSE “mad cow” is also a TSE

- Transmissible
- Fatal
- No cure known
- The pathogen is an abnormal form of the prion protein

# Scrapie cases

Mynd: Matvælastofnun

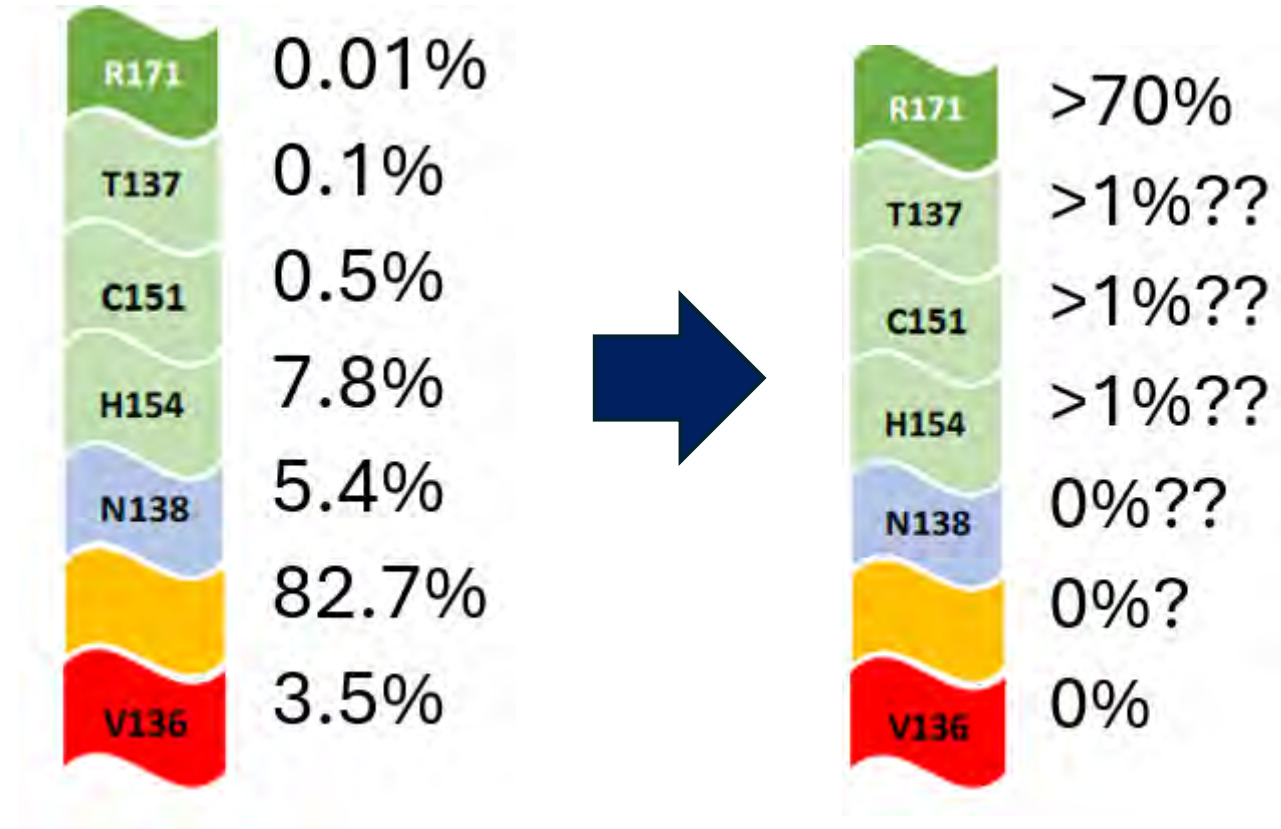

# Genotype of the *PRNP* affects susceptibility

Each animal's *PRNP* genotype consists of two alleles  
7 different alleles of *PRNP* known in Iceland

# How can we make the population resistant?

- Cost
- Time
- Production traits
- Inbreeding
- Genetic diversity

RML

# Breeding against scrapie

Effect of different strategies for introducing resistant genotypes  
estimated with stochastic simulations

Þórdís Þórarinsdóttir  
Jón Hjalti Eiríksson

# Background

- Can we make the population resistant to scrapie by selecting for the  allele?
- Few carriers raises worries:
  - Costly and takes long time
  - Selection for  slows genetic improvement in other traits
  - Inbreeding
  - Loss of genetic diversity

# Methods

Stochastic simulation

Population size 130,000 breeding ewes

30,000 ewes on high-risk areas – 100,000 in low-risk

Population structure mimicking the Icelandic sheep population

 “planted” in a few animals in one flock

The rest assumed wild-type

**13 different scenarios**

# Genotype % in the population by years

# Genetic trend in production traits

The pink line is the Base scenario

Sviðsmynd 1\_l\_gg 1\_l\_uu 1\_m\_gg 1\_m\_uu 1\_l\_ug 1\_m\_ug Grunnur

Sviðsmynd 2\_l\_gg 2\_l\_uu 2\_m\_gg 2\_m\_uu 2\_l\_ug 2\_m\_ug Grunnur

Scenarios with intense selection everywhere

Scenarios with lower intensity of selection in low-risk areas

# Average inbreeding coefficient

Sviðsmynd 1\_l\_gg 1\_l\_uu 1\_m\_uu Grunnur  
1\_l\_uu 1\_m\_gg 1\_m\_uu

Scenarios with intense selection everywhere

Scenarios where ARR/-breeding rams are replaced every year → **lowest inbreeding**

Sviðsmynd 2\_l\_gg 2\_l\_uu 2\_m\_uu Grunnur  
2\_l\_uu 2\_m\_gg 2\_m\_uu

Scenarios with lower intensity of selection in low-risk areas

## Rate of increased inbreeding in generation (%)

Limit <1%

Scenarios with intense selection everywhere

Scenarios with lower intensity of selection in low-risk areas

Base 0.153

## Effective population size

Limit >50

Scenarios with use of R171/- rams limited to 1 year

# ~ Conclusions ~

## Despite few ARR carriers in the beginning:

- Making the population resistant to scrapie in less than 20 years is possible
- Negative impact on genetic improvement and inbreeding
- Limiting the use of the same ARR/- breeding rams to 1 year in the beginning is an effective way to reduce risk

# Estimated breeding value (EBV) for relative scrapie susceptibility

Jón H. Eiríksson

Þórdís Þórarinsdóttir

Egill Gautason

# Objectives

We cannot genotype all sheep – and we don't have to!

1. Predict *PRNP* genotypes in ungenotyped sheep based on pedigree
2. Compile existing estimates of the relative scrapie susceptibility (RSS) associated with different *PRNP* genotypes
3. Calculate estimated breeding value (EBV) of RSS based on the predicted genotype + genotypic RSS

# EBV for RSS - methods

(Estimate of) number of alleles  $\hat{\gamma}_{i,j}$

Multi-trait linear model based on pedigree

Estimate of susceptibility of the genotypes  $\hat{g}_{k,l}$

Meta-analyses of published odds-ratio (as far as they are available)

10 papers found on PubMed

# RSS from meta-analysis. The numbers are $\ln()$ of odds ratio relative to ARQ/ARQ in affected flocks

Coloured is based on data

Extrapolated, assuming T137 is dominant, N138=ARQ and C151=AHQ

	V136		N138	H154	C151	T137	R171
V136	2.45						
	1.81	0					
N138	1.81	0	0				
H154	-2.4	-1.48	-1.48	-1.94			
C151	-2.4	-1.48	-1.48	-1.94	-1.94		
T137	1.81	-3.01	-3.01	-3.01	-3.01	-3.01	
R171	-0.26	-3.53	-3.53	-3.65	-3.65	-3.01	-4.74

# Accuracy of predicted breeding value of scrapie susceptibility for in ungenotyped sheep

Correlation between true BV and EBV

Scenario	Description
rand	5% genotyped at random
hr20	20% of rams genotyped at random
hr40	40% of rams genotyped at random
hr40x1	40% of rams genotyped at random, 5% pedigree errors
hr40x2	40% of rams genotyped at random, 10% pedigree errors
hr40y1	40% of rams genotyped at random, 1% genotyping errors
hr40y2	40% of rams genotyped at random, 2% genotyping errors

# Accuracy – real data

---

Assumed heritability	Female 2021 to 2022		2022		2023	
	Accuracy	Dispersion	Accuracy	Dispersion	Accuracy	Dispersion
0.90	<b>0.64(0.01)</b>	1.09(0.02)	<b>0.65(0.01)</b>	1.06(0.02)	<b>0.46(0.01)</b>	1.01(0.02)

---

# Conclusions in scrapie EBV

Useful tool for, e.g. selecting replacement ewes or prioritizing sheep for genotyping

Genotyping still important for ram selection and for tracing rare alleles

# Final points

## This work has impact

The scrapie eradication plan is partly based on the simulation results

The scrapie EBV will be published next fall

## Future perspectives

More results on the T137, C151 alleles may change strategies

Monitoring the progress – effect on genetic variation in particular

Thank you
